nterfacial passivation raise both initial efficiency and stab

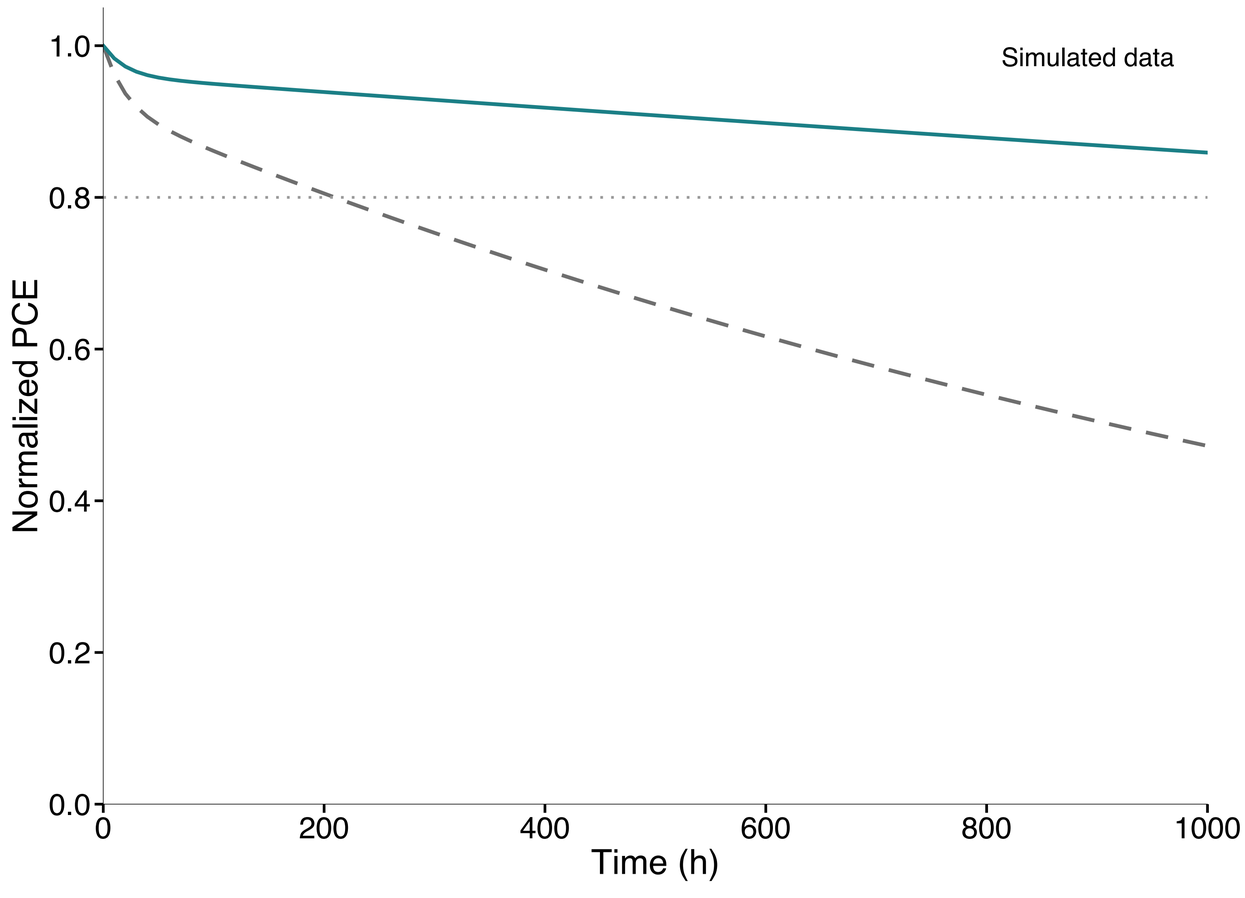

Modified device shows higher PCE and retention in simulated teaching data

What we changed

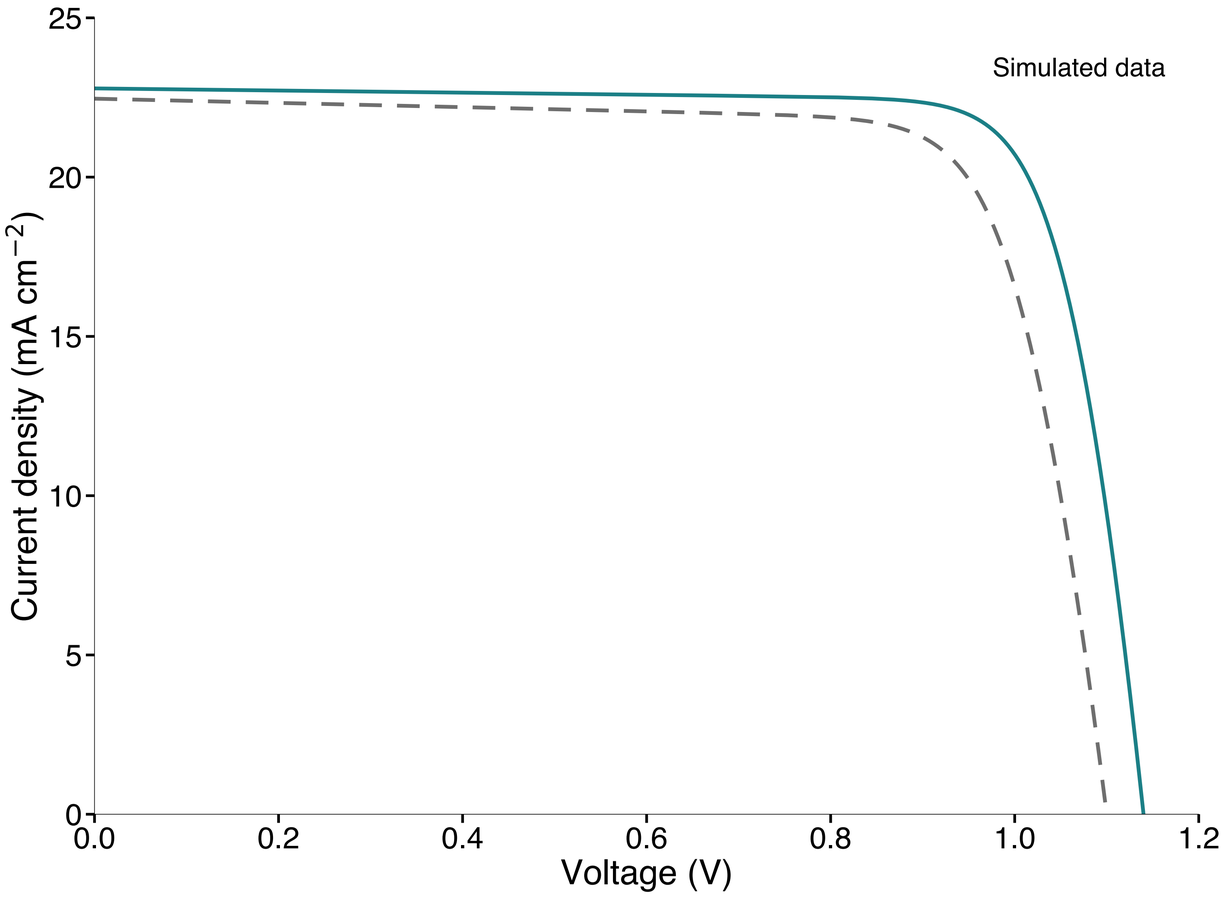

Schematic, not to scale

After 1000 h, modified retains ~86% of initial efficiency

Modified device PCE rises from 19.2% to 21.0% (simulated data)

- Planar n-i-p stack; passivation at interface (modified)
- Simulated reverse-scan J–V (single-diode model)
- MPP tracking stability under illumination (simulated)
- Colour: grey = control, teal = modified
- One representative curve per group
